Background and Aims

Glial fibrillary acidic protein (GFAP) in serum is a promising biomarker to differentiate between acute ischemic stroke (AIS) versus intracerebral hemorrhage (ICH). We evaluated its diagnostic value through a systematic review and individual patient data (IPD) meta-analysis.

Methods

We performed a systematic search in PubMed database until November 2018 for publications that evaluated GFAP to differentiate AIS-ICH within the first 4.5 hours from symptom onset. Due to different assays employed for GFAP measurement, we standardized levels by calculating the Zscore. We used standardized IPD to assess its association with patient and stroke characteristics and factors related with GFAP measurement.

PubMed Search (until Nov/30/2018) 1250 titles after initial search 1229 studies excluded due to fulfill any exclusion criteria described in PROSPERO protocol Potentially elegible: 21 articles Excluded articles: 5articles 1 all samples extraction from onset superior 4.5h 2 studies with only subarachnoid haemorrhage 1 study review 1 study ongoing 16 studies to collect all data for analysis Excluded articles: 12 articles 5 authors didn't answer after two requirements 1 impossible defining time of samples extraction from onset 1 Didn't find any contact email 1 refused to participate 4 cohorts from the same

Results

IPD were provided from four studies (figure 1). Baseline of different studies are shown in table 1. GFAP blood levels were significantly elevated in ICH patients (figure 2 and figure 3). Both stroke types showed a positive correlation between baseline stroke severity and GFAP concentrations (correlation coefficient and p value: 0.267, p<.0001; 0.302, p=0.004; for ischemic and ICH, respectively). No correlation was found between time to sampling (TTS) and GFAP levels (correlations coefficient and p value: 0,08, p=0,24; 0,09, p=0,38; for AIS and ICH, respectively). Others factors associated with GFAP levels were presence of dyslipidemia (p=0.017) and hematoma volume (r=0.43, p=0.004), in AIS and ICH patients, respectively.

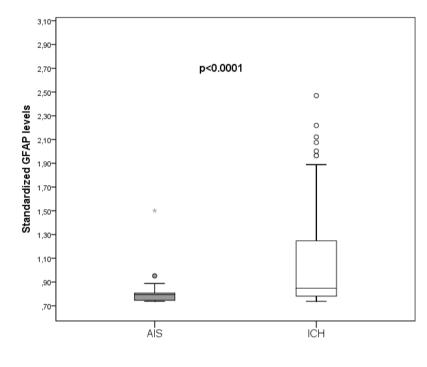

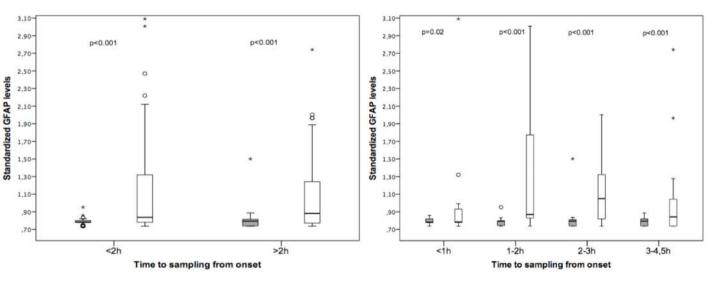

Figure 2: GFAP serum levels according stroke type. GFAP blood levels were significantly elevated in ICH patients [0.840 (0.781-1.239), 0.794 (0.741-0.806); median and interquartile range, for ICH and AIS, respectively.

GFAP ICH	0.71 (0.17-2.44)	0.06 (0.00-	2.17 (0.55- 10.12)	0.08 (0.04-0.68)	0.85 (0.78-
Outcome data	No	mRS 1 week	mRS 1 week	mRS 3 month AIS only	-

Table 1: Baseline features of studies. GFAP valuesare shown as standardized concentrations.

Figure 3: GFAP serum levels according stroke type. After dividing the sample into two and four groups depending on TTS, respectively. Both analysis show significative differences.

Conclusions

- □ The present IPD confirmed that GFAP serum levels were higher in ICH than AIS patients.
- Additionally, higher levels were associated with stroke severity regardless stroke subtypes.
- □ There was no association with TTS within first 4.5 hours, so GFAP could be a valuable tool in this framework.
